**ACTIVE MATRIX ORGANIC LIGHT EMITTING DIODE FLAT-PANEL
DISPLAY**

FIELD OF THE INVENTION

5 The present invention relates to organic light emitting diode (OLED) flat-panel displays and, more particularly, to means for compensating for aging effects in the light emitting elements of an active matrix flat-panel OLED display.

BACKGROUND OF THE INVENTION

10 Organic light emitting diode (OLED) flat-panel display devices are proposed for use in conjunction with computing devices and in particular with portable devices. Over time, the efficiency and effectiveness of the displays changes and the quality of the display, particularly for sensitive applications such
15 as imaging, declines. This decrease in quality is due to changes over time in the materials comprising the display, degradation in electronic components, and the like.

 In particular, OLED display devices suffer from changes in the organic light emitting materials within the display. The changes affect the
20 efficiency and brightness of the display. These changes may also be color dependent, that is the changes affect the different colors in the display device in different ways so that over time not only does the power efficiency of the display device decrease, but the color balance changes. These changes can result in an inferior display with poor brightness and color rendition.

25 In an active matrix type OLED display (as shown in Fig. 1), each light emitting element is individually controlled by an associated control circuit that includes a capacitor 4 that stores a data signal. The capacitor is charged through a transistor 2 connected to data line 1 and a select line 3. A transistor 6 is connected in series with the light emitting element 7 between a power supply 8
30 and ground. The capacitor is connected to the gate of the transistor to control the current passing through the light emitting element based on the amount of charge stored on the capacitor, thereby determining the brightness of the light emitting

09858109 051501

element. When the response of the light emitting element to current drops due to aging of the light emitting material, the light emitting element can be recalibrated by increasing the signal stored on the capacitor in the control circuit or by increasing the power supply voltage. In either case intervention is required.

5 There is a need therefore for an improved method of automatically correcting the brightness and color rendition of an active matrix OLED flat-panel display.

SUMMARY OF THE INVENTION

10 The need is met according to the present invention by providing an active matrix OLED flat-panel display that includes a plurality of light emitting elements and associated control circuits; a programmable power supply connected to the control circuits; a sensor for sensing the light output of one or more light emitting elements to produce a feedback signal; and a display
15 controller responsive to the feedback signal for programming the programmable power supply to compensate for changes in the light output from the light emitting elements.

ADVANTAGES

20 The present invention has the advantage that it automatically corrects the color balance of a color and brightness of a display system over time, as the materials within the display degrade.

BRIEF DESCRIPTION OF THE DRAWINGS

25 Fig. 1 is a schematic circuit diagram showing a prior art active matrix light emitting pixel;

 Fig. 2 is a diagram showing an improved voltage controlled display according to the present invention;

 Fig. 3 is a diagram showing an improved voltage controlled display
30 with multiple colors according to the present invention; and

Fig. 4 is a diagram showing an improved voltage controlled display with multiple colors integrated into a common substrate or package with the display according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Flat-panel display devices degrade over time as they are used. In particular, the light emitting materials become less efficient resulting in a loss of brightness and accuracy in color rendition. For those flat-panel display devices for which the brightness of each light emitting element is voltage or current controlled, the present invention provides a system wherein a programmable power supply is used to modify the operational characteristics of the display device.

Referring to Fig. 2, a flat-panel display system 10 includes a flat-panel display 12 with light emitting elements 14, a display controller 18 having a programmable power supply 20, and a sensor 24. The sensor 24 detects the brightness of the light emitted or controlled at a light element 14 in the display and provides this information to the controller 18. The controller then programs the power supply 20 with the correct voltage or current parameters necessary to maintain the appropriate brightness from the light emitting elements 14.

A more complex embodiment for use in color flat-panel devices is shown in Fig.3, where separate sensors 25, 26 and 27 are shown for light emitting elements 15, 16 and 17. The sensors 25, 26 and 27 provide signals to the display controller 18. The controller programs the power supplies 21, 22 and 23 that then modify the operational characteristics of the light emitting elements within the display device through power lines 31, 32 and 33. Each of the light emitting elements 15-17 associated with the sensors 25-27 providing signals to the display controller 18 programming the power supplies 25-27 are each typically one of the colors of the display, for example, red, green, and blue. These sensors may generate separate signals applied to the controller over separate lines, or the signals may be multiplexed and supplied to the controller over a shared signal line.

As each of the light emitting elements changes over time, each of the power supplies driving the associated elements can be independently modified to provide the appropriate brightness consistent with maintaining the color balance of the device. For example, if the red elements become half as efficient, the power provided to the red elements can be increased as necessary to compensate, thus maintaining the original brightness and color balance. The ability of the present invention to compensate for changes in the efficiency of the light emitting elements is limited to the maximum power (voltage or current) each element can withstand. Hence, if, as in the previous example, the red elements cannot withstand a greater power, the green and blue power can be reduced to maintain a consistent color balance at the cost of brightness.

The components of the present invention may be implemented internally within a flat panel display, for example upon a common substrate or within a common package, or implemented externally in a separate integrated circuit or printed circuit board. In particular, the programmable power supplies may be implemented within common packaging or upon a common substrate as the flat-panel display to minimize the number of electrical leads necessary for the flat-panel display, as shown in Fig. 4. The individual power supplies can create their separate power sources from a common power source 30 provided to the flat-panel display. If the power for each separate set of elements is derived externally to the flat-panel package, a lead for each power supply is necessary.

If the power supply components are internal to the flat-panel device, they are readily accessible through address, data, and control lines 34 using conventional digital logic and analog power devices. If the components are external to the display device, conventional integrated circuit technology and packaging can be utilized to provide programmable voltage circuitry within the integrated circuit. Current and voltage control devices are well known in the prior art and are used in commercial products.

In a preferred embodiment, the invention is employed in a device that includes Organic Light Emitting Diodes (OLEDs) which are composed of small molecule polymeric OLEDs as disclosed in but not limited to US Patent No. 4,769,292, issued September 6, 1988 to Tang et al. and US Patent No. 5,061,569,

0958109 051504
105150 50185860

issued October 29, 1991 to VanSlyke et al. Many combinations and variations of organic light emitting displays can be used to fabricate such a device.

The invention has been described in detail with particular reference to certain preferred embodiments thereof, but it will be understood that variations
5 and modifications can be effected within the spirit and scope of the invention.

PARTS LIST

- 1 data line
- 2 transistor
- 3 select line
- 4 capacitor
- 6 transistor
- 7 organic light emitting diode
- 8 power supply
- 10 flat-panel display system
- 12 flat-panel display
- 14 light emitting element
- 15 colored light emitting element
- 16 colored light emitting element
- 17 colored light emitting element
- 18 display controller
- 20 programmable power supply
- 21 programmable power supply for group of color elements
- 22 programmable power supply for group of color elements
- 23 programmable power supply for group of color elements
- 24 sensor
- 25 sensor for color light emitting element
- 26 sensor for color light emitting element
- 27 sensor for color light emitting element
- 30 power lead
- 31 power lead for color elements
- 32 power lead for color elements
- 33 power lead for color elements
- 34 address data and control lines
